

Naloxone Myths

Debunked

Indiana State
Department of Health
Trauma and Injury Prevention

Myth #1:

Naloxone encourages substance users to take more drugs.

FACT: Research has shown that naloxone does not lead to more drug use or riskier drug use.¹ In fact, some studies have shown that naloxone results in a decreased use of opioids.² Naloxone also causes opioid withdrawal symptoms, which is an effective abuse deterrent.

Myth #3:

Naloxone makes people violent.

FACT: One of the most common side effects of naloxone administration in patients is confusion and disorientation.⁴ It is rare for someone to wake up from an overdose and become combative.⁵ This is especially rare if naloxone is administered by someone they know and trust.

Myth #5:

Naloxone is taking too much of the public's funds and attention.

FACT: Every medical and emergency service has an associated cost. Substance use disorder and overdose is a recognized health condition that deserves attention. In 2017, more than 72,000 Americans died from a drug overdose.⁶ Many of these deaths could have been prevented by naloxone.

Myth #2:

Naloxone prevents substance users from seeking treatment.

FACT: There is no evidence to support that naloxone prevents substance users from entering a treatment program.³ In fact, the near-death experience often serves as a catalyst to seeking treatment and maintaining recovery.

Myth #4:

Only doctors can prescribe naloxone.

FACT: The Indiana State Health Commissioner issued a standing order in 2016 that allows anyone to go directly to a pharmacy and purchase naloxone without having to obtain a prescription from their doctor.

Myth #6:

First responders administer naloxone to the same people over and over again.

FACT: Research has shown that the majority of overdose patients do not have repeated overdose events.⁷ Even so, public health officials believe that every life is worth saving, even if that requires repeated administration of naloxone to the same patient.
